TeX math in Markdown

Turn on `math: true` in the frontmatter and write formulas with TeX dollar syntax. Inline math goes between single dollars, display math between double dollars. The TeX is converted to MathML and rendered by the same engine that powers the `<math>` HTML example, so it inherits Formula tagging and, under PDF/UA-2, the MathML associated file.

Inline math

The mass-energy equivalence $E = mc^2$ sits inline with the prose, as does a variable like x or a subscripted one like a_i. Greek letters work too: the angle θ and the wavelength λ.

Display math

The quadratic formula, set as a display equation:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

A summation in display style, where the engine enlarges the operator and places the limits above and below:

$$\sum_{i=1}^{n} i = \frac{n(n+1)}{2}$$

Fences, floors and primes

Delimiters written with `\left` and `\right` stretch to the content they enclose, floor brackets come from `\lfloor` and `\rfloor`, and primes use the TeX apostrophe shorthand. An integral keeps its scripts beside the operator (TeX treats it as nolimits), unlike the stacked sum above:

$$f'(x) = \left(\frac{x}{2}\right)^2 + \left\lfloor \frac{n}{2} \right\rfloor + \int_0^1 x^2 \, dx$$

Predictable dollars

The strict dollar rule keeps prose safe: prices such as $5 and $10 are not formulas, because a closing dollar may not be followed by a digit and an opening dollar may not be followed by a space. A literal `$x$` inside a code span also stays verbatim.
